Marine Monitoring

- Legislated role to manage it's estate
- Establish long-term MER on ecological assets
- Conduct LTM on key assets & pressures to support management
- Condition-Pressure-Response model

Monitoring in SBMP

○ Water quality

- Nutrients at Monkey Mia
- Modelled in situ seawater temp (mIST)

○ Seagrass

- In situ transects (shoot density)
- Drop-camera (% cover)
- Remote sensing imagery (extent)

○ Mangroves

- Spatial extent
- Projected foliage cover

○ Corals

- In situ transects (% cover)
- Recruitment (tiles)

○ Fish

- DOVs & BRUVs in a range of habitats (abundance)

Water Quality

- Pressure = Terrestrial run-off
 - Monkey Mia
- Indicator = Nutrients
 - Nitrogen, Phosphates
- Indicator = Pathogens
 - *Enterococci* spp.
- Trend = Stable

Seawater Temperature

Seagrass

- Pressure = ↑ Seawater Temperature
- Indicator = Shoot density, canopy height, morphology metrics, community composition, % cover, spatial extent*
- Trend = **Declining***
 - Shoot density = stable for *Posidonia*
 - Canopy height = decreasing for *Posidonia*
 - Morphology metrics = insufficient data for *Amphibolis*
 - Community composition = decrease in *Amphibolis*
 - % cover = decrease in *Amphibolis*

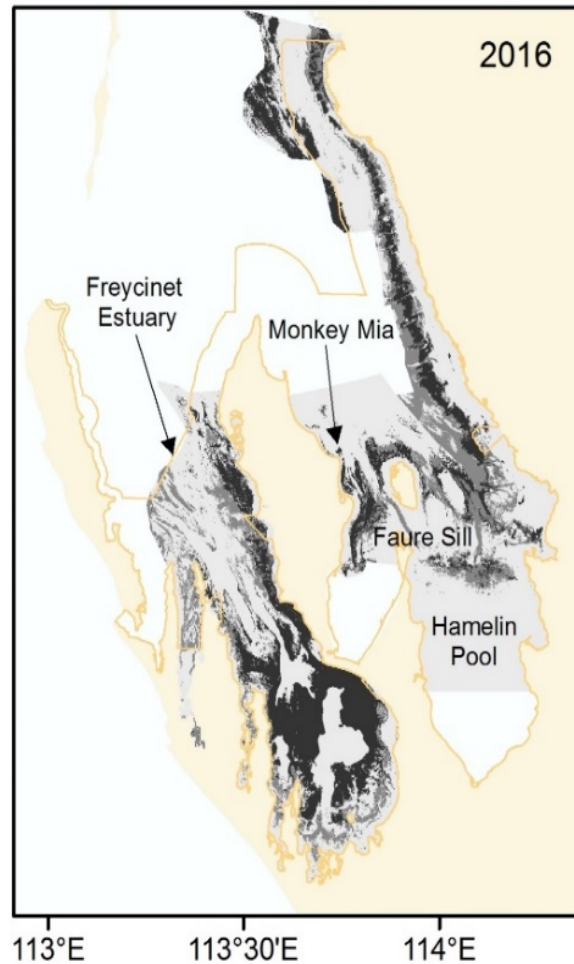

Seagrass

Graticule shown at 30 minutes intervals
Source Imagery: Landsat 7 TM and 8 OLI,
USGS (glovis.usgs.gov/)

0 25 50 100 Kilometres

Legend

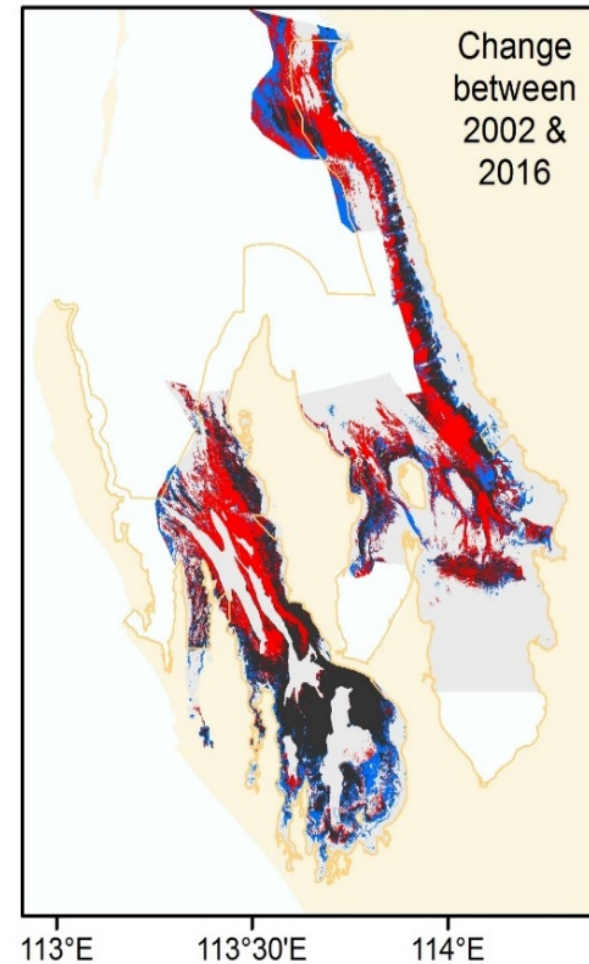

- Marine Park Boundary
- Land
- Unprocessed

Seagrass Extent

- Sand
- Dense Seagrass
- Sparse Seagrass

Seagrass Change

- Other Stable
- Seagrass Stable
- Seagrass Loss
- Seagrass Gain

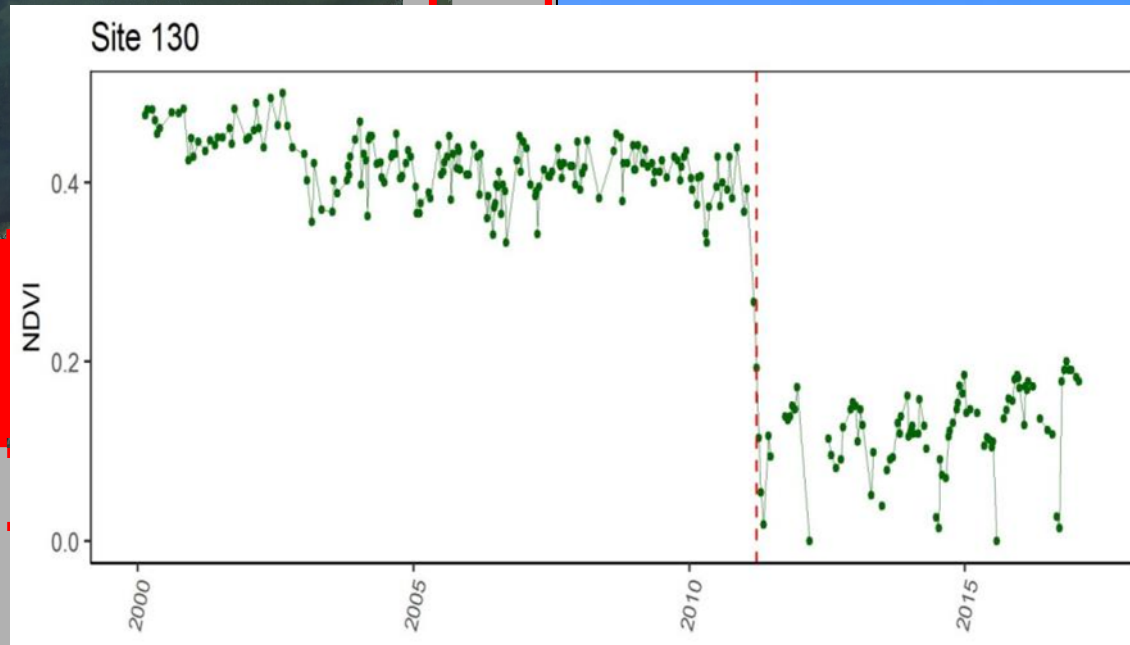

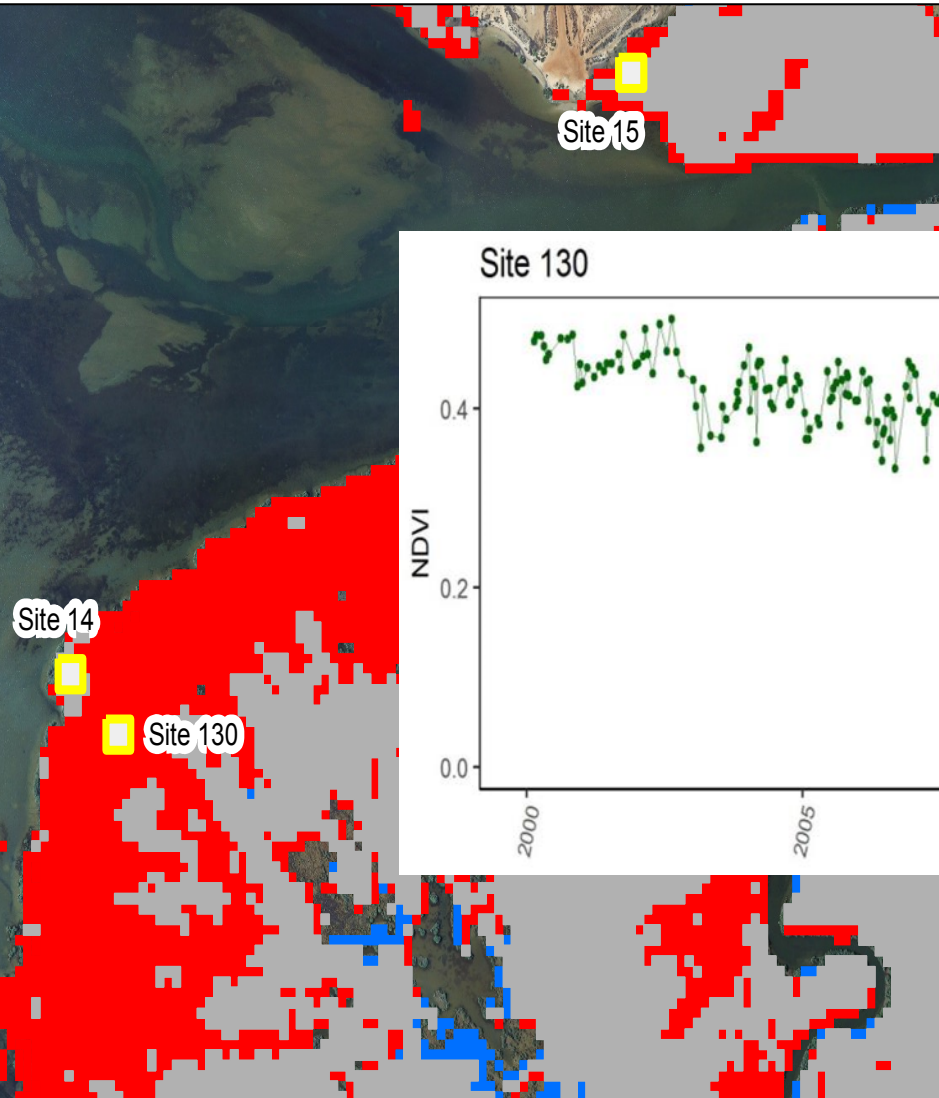

Mangroves

- Indicator = Spatial extent*
- Indicator = Canopy density
- Trend = Declining*

Mangroves

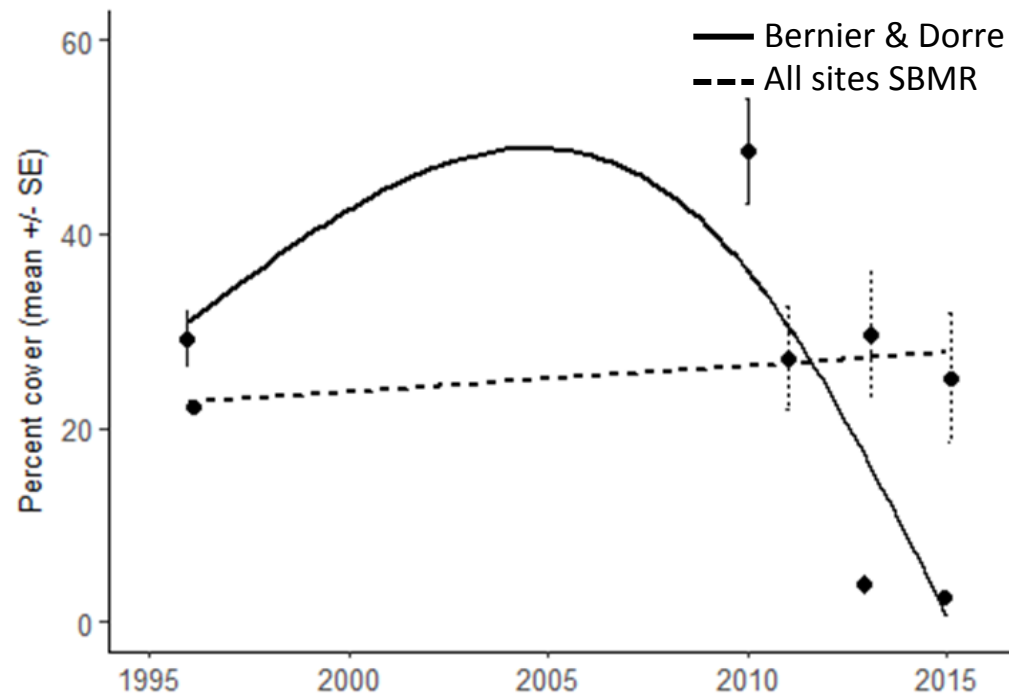

Mangroves

Carnarvon Coast

Coral

- Pressure = ↑ Seawater temperature
- Indicator: *mIST*
- Trend = Increasing
- Indicators = Coral cover, community composition, recruitment
- Trend = Uncertain

Coral

Temporal differences:

Cover at Bernier and Dorre islands declined by ~90% since 2010 (Ningaloo Niña), especially *Acroporidae*

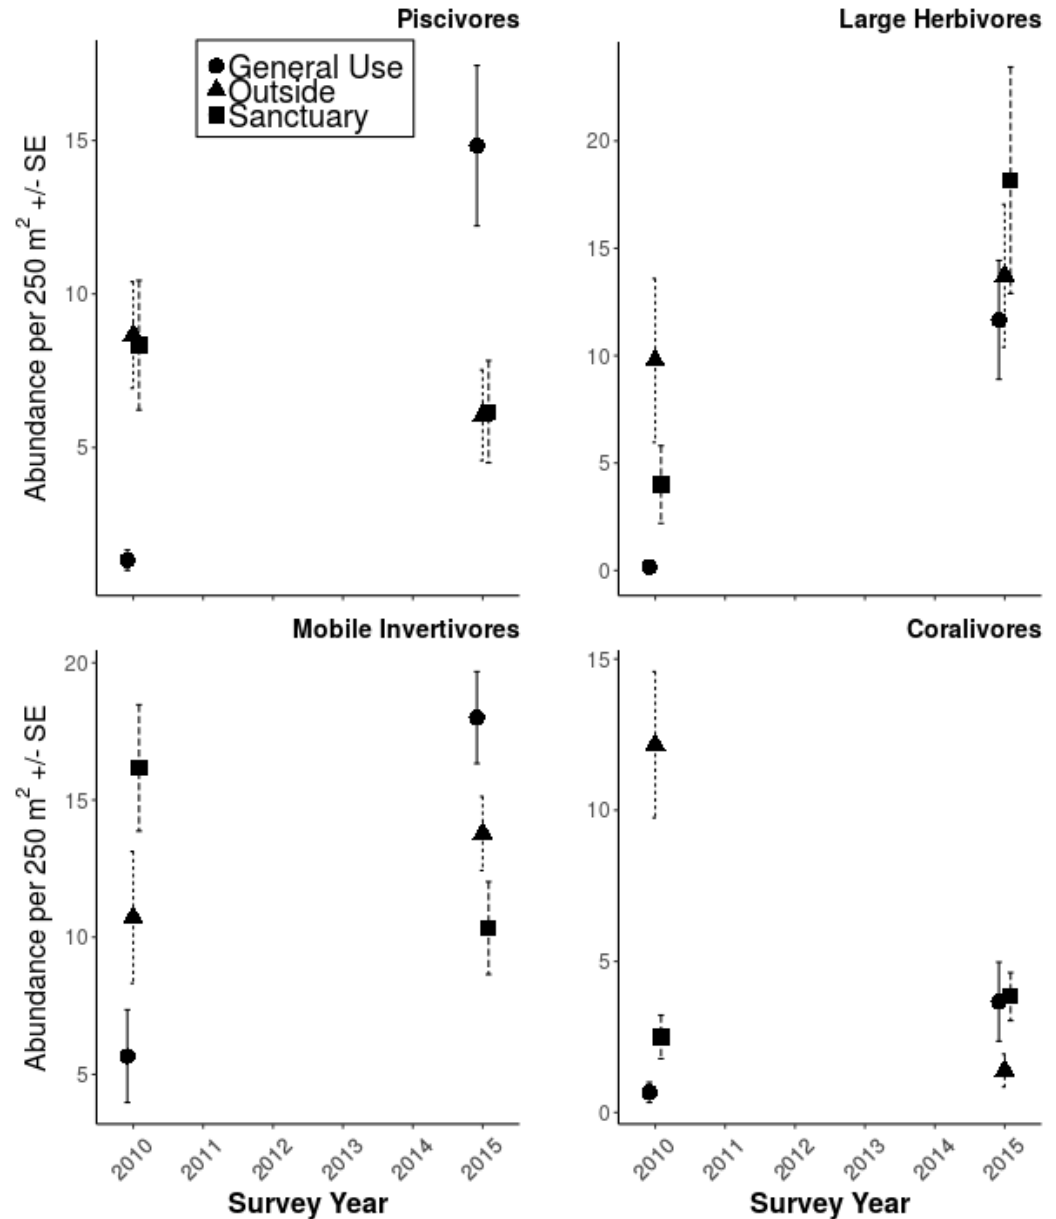

Coral

- Overall: coral cover in the marine reserves remained stable across the survey period (1996-2015) at 15-25%
- Confidence for the whole area is low (temporal gap between surveys in 1996 & 2010/2011) but will increase over time

Fish

- Indicators =
Abundance, Species richness, Community composition
- Pressures =
Charter/ commercial/ rec fishing & Habitat loss
- Trend = Uncertain

Fish

- Decline in corallivores at Bernier/Dorre Is. likely associated with declining coral condition
- Commercial & charter fishing **declined** (2008-2015) & recreational fishing remained **stable** (2011-2014)
- Confidence in finfish community condition will improve as the program starts to include non-coral habitats & spatial/ temporal resolution improves

Summary

- **Temperature** = key pressure, mangroves & seagrass extent/condition **declining**, unclear coral cover & finfish community trends
- Massive area (748,725ha) makes it difficult to have a high resolution program (coverage of sites + regular sampling intervals)
- Reliance on remote sensing becoming a valuable supplementary tool
- More details in: “Ecological monitoring in Shark Bay marine reserves report” (due this year)

Going Forward

- Priorities: sediment quality, water quality, filter feeders, mangrove & seagrasses, microbial communities
- What are the ecological consequences of mangrove, seagrass & coral loss (turtles, dugongs, fish, invertebrates)?
- Susceptibility for mangrove loss in a changing global climate: high resolution topography; sediment porewater salinity; sediment accommodation; sea level rise; migration
- Repeated time-series *high resolution* benthic mapping

- How does a change in composition & extent of mangroves & seagrass influence their ecological function?
- Identify & assess areas with high resistance &/or recovery potential
- Assess the level of connectivity of Shark Bay with other regions
